

CorpusCast

CorpusCast is going to be a fishing dashboard focusing on the Corpus Christi area. The app is going to have a couple of well known local fishing spots , and it will show the weather conditions for the area. It will also provide recommendations for how to fish, when, and what fishing rigs to use. The main target audience of this app will be anglers in the Corpus Christi area who are looking to plan out their fishing trip. I will be using the Open-Meteo public weather API in order to asynchronously get information such as temperature and wind speeds. CorpusCast will then use that information, along with preset data about each spot that I will store in a JSON, to give the user metrics about that fishing spot along with recommendations on how to fish it.

The main workflow of the app will be the user enters the page, and then chooses a fishing spot that is displayed. The weather data, and recommendation will then be loaded and processed, and displayed to the user in an easy to digest format. I will also enable the ability for the user to save their preferences in localStorage. The app will use interactive visuals in order to better demonstrate to the user what fishing rigs to use, along with how the weather is looking and feeling. CorpusCast will have basic accessibility features to ensure that all users are able to interact with the website and understand its content. In order to keep the scope limited to be able to complete the project in a few weeks, I will use a limited number of local fishing spots, and keep the fishing recommendations basic but effective. It will not be extremely in depth rather a more general set of rules that will help the angler make their fishing choices. I will also keep the visuals simple and straightforward, instead of trying to have extravagant effects.
